- 1) FBDS (Function Before Data Source) - before sending the model to the data source, you can calculate the parameters and check the model parameter and give an error if it does not match, thereby interrupting the sending of the model to the data source.
- 2) CloneStreamModelForSuccess - abstract stream class, the purpose of which is to define a specific stream type and standard values model and list model. And also this class is required so that the ViewModel can be reused for new models inherited from the base model.
- 3) (List/Model)ForNamed(TIP/NP) - an abstract class for defining a derived type from DataSource methods. This class is required so that the DataSource can be reused for new models inherited from the base model.
